#### **3D Geometry**

#### 13 February 2007 CMPT370 Dr. Sean Ho Trinity Western University

## **Coordinate-free geometry**

#### Cartesian geometry:

Points are locations in space (x,y,z)

Tied to a particular coordinate system

Euclidean (coordinate-free) geometry:

- Points exist regardless of the coordinate system
- e.g.: two triangles are identical if all three legs are same length

Regardless of where in space the triangle is

### Scalars, vectors, and points

# Three basic elements in geometry Scalars (α)

- Addition, multiplication
- Associativity, commutativity, etc. (field)
- No geometric properties
- E.g., reals, complex numbers
- Vectors (v)
- Points (P)

12+0.3i

CMPT370: geometry

-17.3

Vectors have two attributes:
Direction
Magnitude
No position
Physically-inspired definition
e.g., force, velocity, directed line segments

Every vector v has an inverse -v

There is a zero vector (zero magnitude)

Adding two vectors gives another vector u+v = w
 u+v
 Vectors can be multiplied by scalars αv = w

CMPT370: geometry

#### Points

Location in space (no direction)
Relationships between vectors and points:

Subtracting two points gives vector: P - Q = v
Adding a vector to a point: Q + v = P

### **Affine spaces**

Combine a point (origin) with a vector space • Vector-vector addition: u + v• Scalar-vector multiplication:  $\alpha * v$ • Point-vector addition: P + v• Scalar-scalar operations:  $\alpha + \beta^* \gamma$ For any point P, let • 1 \* P = P• 0 \* P = (zero vector) 0

Parametric definition of a line:

All points P that pass through a point P<sub>0</sub> in the direction of the vector v:

• 
$$P(\alpha) = P_0 + \alpha^* v$$

Alternate forms in 2D:

• Parametric:  $x(\alpha) = (1 - \alpha)x_0 + (\alpha)x_1$ ,

 $\mathbf{y}(\alpha) = (1 - \alpha)\mathbf{y}_0 + (\alpha)\mathbf{y}_1$ 

- Explicit: y = mx + h
- Implicit: ax + by + c = 0

A ray is one side of a line:
All points P(α) = P<sub>0</sub> + α\*ν P<sub>0</sub> for which α ≥ 0
A line segment between points P<sub>0</sub> and P<sub>1</sub> is
All points P(α) = (1-α)P<sub>0</sub> + (α)P<sub>1</sub>
P for which 0 ≤ α ≤ 1

We can generalize from lines to curves:
 Curves are one-parameter geometric entities P(α)
 Often have a starting point P<sub>0</sub>
 α can be thought of as time
 Curve describes motion of a point through time

#### **Surfaces**

 $\square$  Curves  $P(\alpha)$  have one parameter  $\alpha$ **Surfaces**  $P(\alpha, \beta)$  have two parameters  $\alpha, \beta$ • Linear functions of  $\alpha$ ,  $\beta$  give planes and polygons A plane in 3D can be defined by • Point + 2 vectors:  $P(\alpha, \beta) = P_0 + \alpha u + \beta v$ • Or 3 points:  $P(\alpha, \beta) = P_0 + \alpha(Q - P_0) + \beta(R - P_0)$ Q • R 13 Feb 2007 CMPT370: geometry

#### Normal vectors

Every plane has a vector n which is normal (perpendicular, orthogonal) to it

- Use cross-product:  $n = u \times v$
- Unit normal is the normal vector which has magnitude 1
- Perpendicular means dotproduct is zero: n \* v = 0

12

#### **Convex hull**

The convex hull of a set of points {P<sub>1</sub>, P<sub>2</sub>, ..., P<sub>n</sub>} is the smallest convex area containing the points:

 Convex: connect any two points in the area, the line segment is completely within the area
 "Shrink-wrap" of the points

Points are convex sums of {P<sub>i</sub>}:

•  $\Sigma \alpha_i P_i$ , where  $\Sigma \alpha_i \leq 1$ 

Triangles are the convex hulls of 3 points

## **Linear independence**

• A set of vectors  $\{v_1, v_2, ..., v_n\}$  is linearly independent if

- $\alpha_1 v_1 + \alpha_2 v_2 + ... + \alpha_n v_n = 0$ only when all the  $\alpha_i$  are zero.
- i.e., cannot represent one vector v, as a linear combination of the others

dependent

#### Basis

Any vector space has a dimension: • Max # of linearly independent vectors A basis for an n-D vector space is a set of n vectors {v<sub>i</sub>} such that any vector w in the space can be written as a combination of them:  $\bullet W = \alpha_1 V_1 + \alpha_2 V_2 + \dots + \alpha_n V_n$ • These  $\{\alpha_i\}$  are a unique representation for the vector w with respect to this basis If the basis vectors are unit-length, this unit basis is usually written {e,}

15

#### Frame

A basis is enough to represent vectors, but Holds no position information We use a frame to represent points Basis + a point (origin): affine space • In 3D: frame  $F = (P_0, e_1, e_2, e_3)$ • Any vector  $w = \alpha_1 e_1 + \alpha_2 e_2 + \dots + \alpha_n e_n$ • Any point  $P = P_0 + \beta_1 e_1 + \beta_2 e_2 + \dots + \beta_n e_n$ The representation is the scalar coefficients  $(\alpha_1, \alpha_2, ..., \alpha_n)$  or  $(\beta_1, \beta_2, ..., \beta_n)$ 

#### Midterm 1 on Thu • GUI, parallel Emphasis on lecture material Practice exam on course schedule Lab3 due next week Thu 22Feb OpenGL 3D model viewer Mouse interaction: transl, rot, scale Show rendering speed in polygons/sec You may use CubeView as a base
